

Reckon on it!

A very British trait

David G Rance

As soon as currencies were established, bartering fell out of fashion and multiplication skills were needed to succeed in business. However, for over a century the calculating aid of choice for trade and commerce was the Ready Reckoner and not the slide rule.

Introduction

After the momentous crash of the financial and money markets in 2008 it is ironic to be thinking back to a time when trade and commerce was dominated by someone's ability to do simple mental arithmetic and longhand calculations. Possibly until cheap electronic calculators became readily available in the early 1970's, multiplication was a chore and often error-prone. Imagine the diligence needed to calculate longhand all the invoice lines on a long bill of sale based on imperial rather than metric weights and measures? Even today there is no electronic calculator working directly in fractions or any non-decimal units.

Clearly when he invented the logarithm in 1614 John Napier (1550-1617) revolutionised the way calculating was done. Before logarithms the time-consuming enormity of some calculations took literally years to finish. Arguably without Napier there would have been no:

- Algorithmic Tables
- Ready Reckoners¹
- Slide Rules
- Mechanical Calculators
- Electronic Calculators

From this list, one group rarely gets mentioned: Ready Reckoners. In their heyday each form of calculating aid listed had universal appeal and was widely used. But unlike most of its more famous peers, Ready Reckoners did not rely on repeated additions to do their multiplication [1]. For a time they also enjoyed popularity all over the world.

What are Ready Reckoners?

Unlike most calculating aids, Ready Reckoners do not rely on logarithms and are exclusively a printed aid. According to the Oxford Compact English Dictionary [2] a Ready Reckoner is: "a book, table, etc. listing standard numerical calculations or other kinds of information."

The image shows two pages from a historical Ready Reckoner. The left page is titled '2/9 TWO SHILLINGS & NINEPENCE.' and the right page is titled 'TWO SHILLINGS & TENPENCE. 2/10'. Both pages contain multiple columns of tables for multiplication. Each table has a 'No.' column on the left and a '£ s. d.' column on the right. The tables are arranged in a grid-like fashion, with rows and columns corresponding to numbers from 1 to 12. The right page also includes a '200' column for larger values.

¹ Generically known as pre-calculated tables but some may also be familiar with the French "Barème".

The term "Ready Reckoner" was probably first coined by an Englishman: Daniel Fenning (1714/15-1767) [3]. Fenning was a schoolteacher well-known for his spelling and language aids. He was also a prolific author of textbooks. In 1757 he published: "*The Ready Reckoner, or Trader's Most Useful Assistant*". However, Fenning probably got his inspiration from tables for simple and compound interest published well over a century earlier by Englishman William Webster.

Besides being a book of tables "Reckoner", like the German "Rechner", can also mean an expert at calculating.

Fig. 1: **Front page of Webster's Tables 1634** [3]

Why did Ready Reckoners become popular?

For nearly 400 years the slide rule and pinwheel mechanical calculators made complicated multiplication, and to a lesser extent division, easy. It is less well-known that such calculating aids were ill-suited to the demands of everyday trade and commerce involving imperial and non-decimal units. It is easy to forget that currency decimalisation² is, for many countries, a relatively recent change and even today, not universal.

Fig. 2: **Examples through the decades (for those needing it) of the advancement of currency decimalisation across the world**

² The process of moving to a numerical base ten (decimal system) for managing a currency.

Surprisingly some non-decimal units of currency still exist. The Islamic Republic of Mauritania still has *1 Ouguiya = 5 Khoums* and The Republic of Madagascar still has *1 Ariary = 5 Iraimbilanja*. But non-decimal currency units may never disappear altogether as thanks to J.K. Rowling we now have the UK Wizard currency of *1 Galleon = 17 Sickles = 493 Knuts!*

In the 19th and 20th centuries, besides obviously needing to combine high precision, speed and accuracy, any calculating aid for commerce had to be capable of handling imperial units. It also had to be cheap enough so they could be used daily by an army of shop assistants and clerical workers - "*100 Ready Reckoners can be purchased for the price of one such calculating machine*" [4].

The complicated calculations (answers at the end) they might have faced every day are:

- In a haberdasher or drapers
3 yards, 1 foot and 3 inches of finest woven silk @ 2 shillings and 9 pennies a yard?
- In an ironmonger
1¼ pounds of 2 inch wrought iron nails @ 1½ pennies an ounce?
- In the chancery of a wealthy landowner
annual rent due on a plot of farming land 1 furlong by 2½ chains @ 30 pounds an acre?

Imperial units existed for length, area, volume and mass. The first unit of length dates from 5000 years B.C. [5]. The *Megalithic Yard*, famously used to build the Great Pyramids of Giza, was 829.1 mm long. Until the start of metrication³ in the 18th century there was a plethora of imperial units and exotic names for such units. For example, the English foot was widely used but it was one of more than 300 units just for measuring length [6]. This continued until the British Weights and Measures Act was passed in 1824. Thanks to the extent of the British Empire at the time (see Fig. 6) the act indirectly introduced the same standard for imperial units to many parts of the globe.

<i>Unit</i>	inch	foot	yard	chain	cm	m	km

Fig. 4: **British Imperial Liquid & Dry Capacity Measures Post 1824** [5]

The French Republic started the change from imperial to metric in 1799 but it took several decades to complete the change. Over the years many countries followed France's example. Some opted for a "big bang" change-over whereas others choose to have a period when both the new metric units were allowed alongside their old imperial counterparts. By 1980 most (but not all) parts of the world had made the change to metric (see Fig. 5). Although "folk-lore" means some old and much loved imperial units, like the British "pint of beer", are still in everyday use.

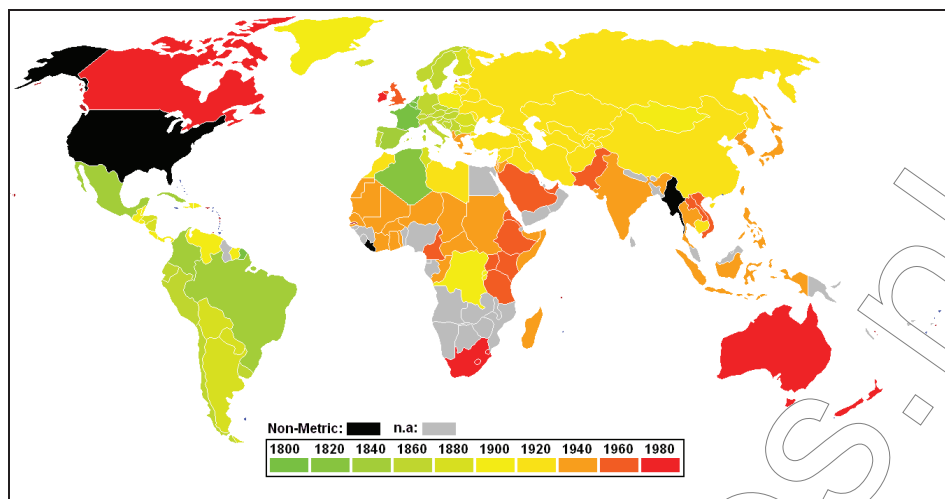

Fig. 5: World Map showing Metrication change-over dates [7]

However, metrication has still to come to the United States of America, the Union of Myanmar (Burma) and the Republic of Liberia.

So put simply, a *Ready Reckoner* is: **a printed book containing a set of pre-calculated values⁴**. The retail unit price of these books, just pennies or at most a shilling or two for special editions, was clearly cheaper than other expensively engineered calculating devices of the day. This was important because it would be handy if shop owners, etc could afford to let every shop assistant or clerk have their own copy. However, it is the Ready Reckoners capacity to provide answers to calculations involving imperial units that is most widely remembered and why they became so popular in certain countries and in particular in what was then "*The British Empire*".

Fig. 6: Areas of the world that at one time were part of the British Empire [7]

⁴ In the new Millennium "*Ready Reckoner*" is also used as a generic term for a computer program proving the computed values for an online calculator – e.g. an online "*Tax Ready Reckoner*".

A ready market for Ready Reckoners

At its peak, at the beginning of the 20th century, the British Empire was the foremost global power and was a major political, linguistic and cultural influence on at least a quarter of the world's population of the day. Consequently the market for Ready Reckoners was worldwide and for many publishers a truly global business. Based on on-line catalogues and relying on classifications like "Ready Reckoner", "Barème", etc (but excluding simple tax tables) a picture of publication numbers of the day over the decades emerges.

Fig. 7: **Number of new Ready Reckoners titles published worldwide per decade from 1749** [3]

Understandably in countries not "blessed" with a rich history of imperial units, there was less demand for specialist Ready Reckoners. But locally printed calculating aids did exist outside the USA and GB.

Fig. 8: **Early 1912 German 390x160x12mm Wichmann Ready Reckoner**

In countries not part of the British Empire, such as Germany and Sweden, the Ready Reckoners published locally were basic multiplication tables, or for currency/date/time related calculations or for units particular to a specialist trade.

Two well-known, 20th century examples are from the Swedish Mult-Divi AB and the German Continentale Büro-Reform (CBR) - including the special CBR edition with the addiator in the back of the book.

Fig. 9: (i). **Multi-Divi** by Wilken Wilkenson
(ii) **CBR Universal Calculator** by Jean Bergmann

So not unsurprisingly, the most prolific publishers of Ready Reckoners were in Great Britain or the United States. Although the American publisher Delbridge, based in St. Louis, is credited with publishing the most titles [3], this is misleading. Delbridge astutely “re-cut and diced” the same Ready Reckoner many times, just suffixing the name of a particular trade or group of users so it became a “new” title. Therefore if this practice is discounted, the Scottish company of Gall & Inglis, with well over 100 known different volumes, was the most prolific 20th century publisher of Ready Reckoners – see the *Appendix*.

Gall & Inglis – a publishing dynasty

Gall and Inglis was an Edinburgh based Scottish firm of printers and publishers. The firm was founded by James Gall (1784-1874) in 1810 and it stayed a family business for 150 years [8]. In the 1820's, based on books for the blind he had seen in France, James Gall designed a font, *Gall type*, for both the partially sighted and the blind [9]. He thought that by creating an embossed font that was also recognisable to the sighted, it would remove some of the stigma of having to have special books for the blind. Regrettably because the resulting embossing proved so dense, the font never caught on and only a few books were ever printed in Gall type.

Fig. 10: **Example of “embossed” Gall type font**

In 1838 James Gall Jnr (1809-1895) joined his father in the publishing business. Understandably for the time, many of the early Gall & Inglis publications had a strong religious flavour. But James Gall Jnr proved to be an excellent cartographer. Surprisingly for a man who later left the business to become a church minister, he had a passionate interest in astronomy. So before he joined the church in 1847, he was responsible for titles like the *"Easy Guide to the Constellations"* and the *"People's Atlas of the Stars"* being published alongside Gall & Inglis' traditional religious texts [10].

The Rev James Gall Jnr and his wife, Mary Campbell, had a son and a daughter. Their son, James (1834-1900) initially joined the business but soon after, for reasons of ill health, he emigrated to Jamaica where he lived until he died [9]. So his place in the business was taken by the Rev James Gall Jnr's future son-in-law. Robert Inglis (1819-1887). He married their daughter, Elisabeth, in 1840. He extended the firms list of existing publications with the works of the classic poets: Scott, Burns, Wordsworth, etc. But when the time came to hand on the family business, as there was no one available from the Gall male line, the business was passed on through the Inglis male line. Interestingly the Gall family name was kept alive by Robert and Elisabeth giving both their sons a middle name of "Gall" – a tradition later passed on to their grandson [11].

JAMES GALL, JR.

By the late 1880's, from an interesting starting mix of religion, poetry and astronomy (star atlases and maps remained part of their portfolio to the end), publishing Ready Reckoners became the mainstay of the business and *"Gall & Inglis (Reckoners) Limited"* was formed. By now Robert and Elisabeth's eldest son, James Gall Inglis (1864-1939), had joined the business. Later, in 1888, his younger brother, Henry (Harry) Robert Gall Inglis (1869-1939) also joined the business. Deceivingly (see *"Best of Both Worlds"*) he only appeared to play a minor role in the business, concentrating on maps and road atlases. James Gall Inglis married Charlotte Hill Kinmont in 1905. Their only son, Robert Morton Gall Inglis (1910-1975), was the last family member to head up the business. Besides taking care of the flourishing Ready Reckoner and maps side of the business, he also shared his father's interest in astronomy. So he continued his father's famous collaboration with A.P. Norton (1876-1955) on the *"Star Atlas"*⁵ and published other astronomy related titles. He and his wife Vera Johnstone had two daughters, Evelyn and Jean, but no sons. Robert Morton Gall Inglis died suddenly from a coronary thrombosis in 1975. But two decades before his death he sold off the family business.

The company only had a short life under its new owners as they finally wound it up in 1960. However, Gall & Inglis (Reckoners) Limited must have continued as a trading entity as some reprints dating from the late 1960's and early 1970's are known to exist. For example, Neill and Co. Ltd. of Edinburgh and Martins Ltd. of Berwick, reprinted and published *"The Ideal Decimal Coinage Reckoner"* in 1969.

⁵ Affectionately known as *"Norton's"* – even today, after eighty years, it has not been superseded.

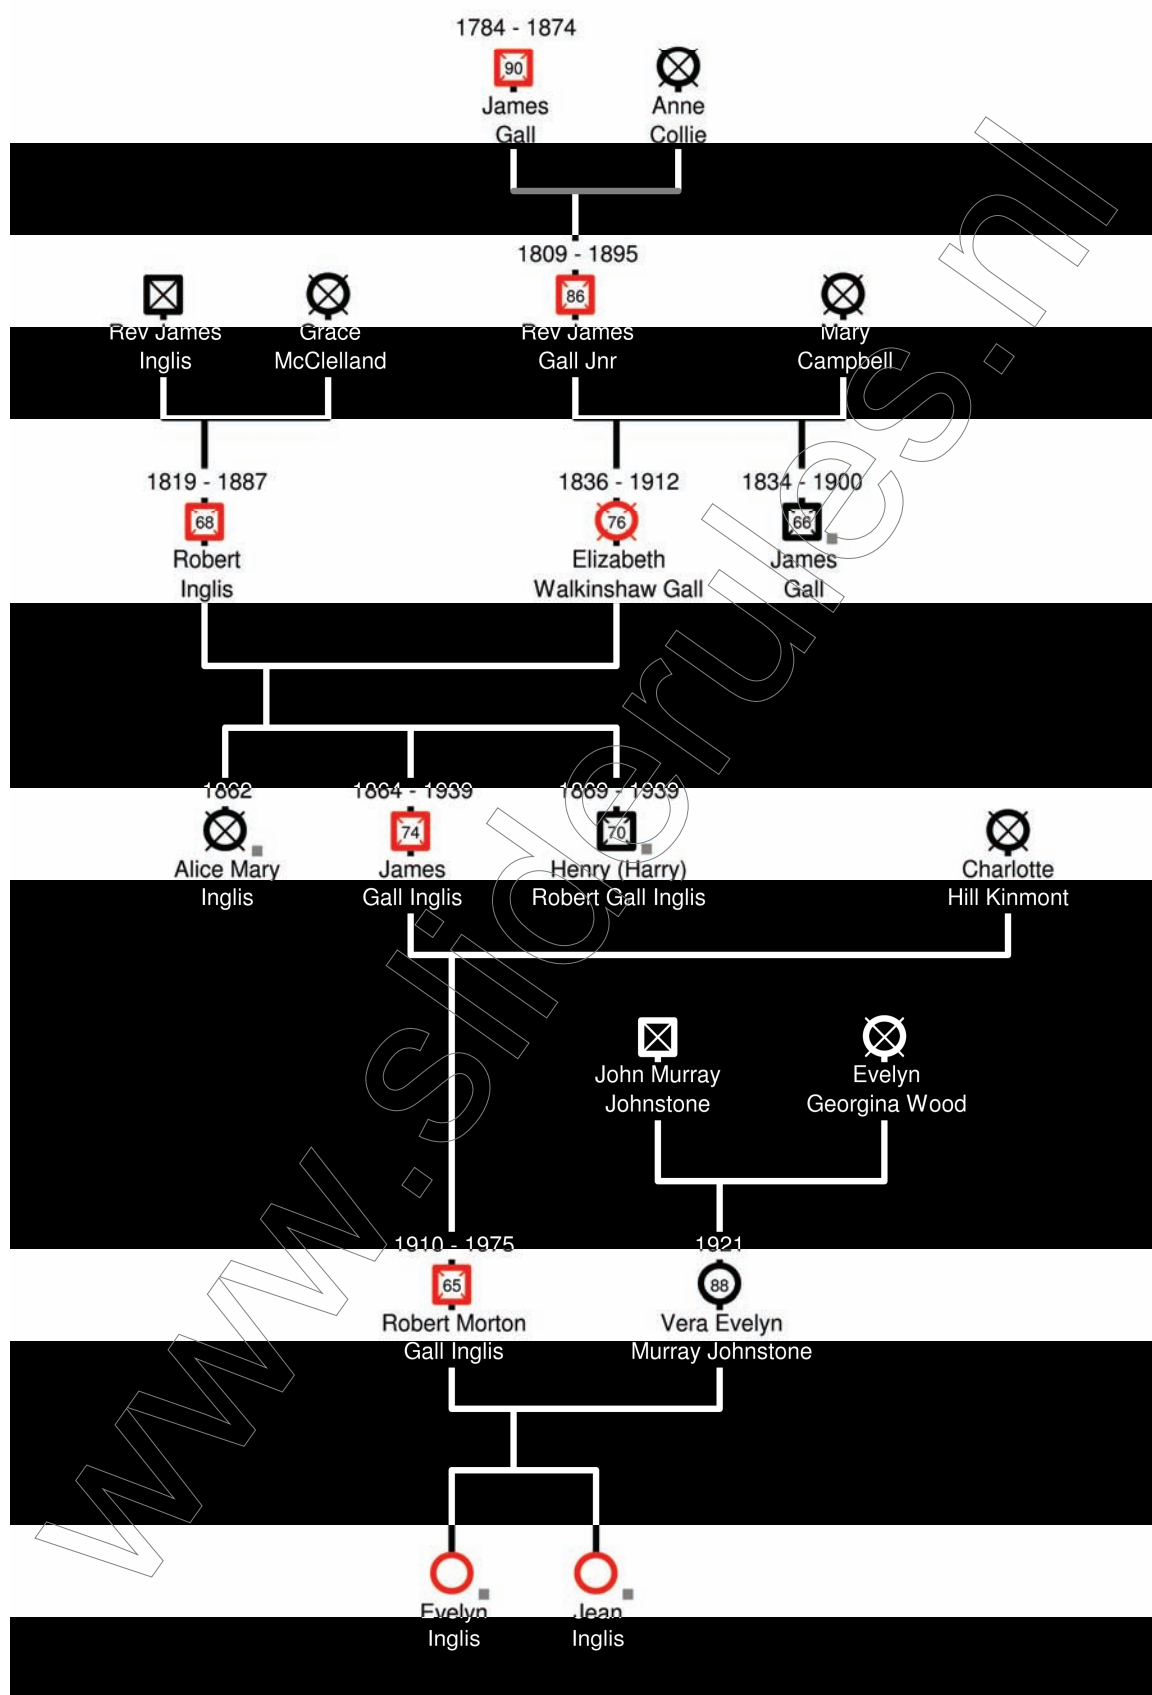

Fig. 11: The Gall & Inglis family tree – main lineage shown in red

Gall & Inglis – the publishing years

Because of the inevitable reprinting and reissuing of Ready Reckoner titles, the year of publication was often not part of any preface or colophon. The *Appendix* is a tabulated inventory of all the known series and the volumes or titles in each series. Sadly it is incomplete because apart from a single copy from 1958 [12], no early Gall & Inglis catalogues could be traced. But even so it shows how clever Gall & Inglis were in devising so many different Ready Reckoners for all sorts of guilds and branches of trade and commerce.

Although imprecise, the Gall & Inglis dynasty itself offers a rough time-line aid to the publication eras. The earlier series' carried the family name of "J. Gall Inglis". Whereas the later series', post 1940, carried the family name: "R.M.G. Inglis" or just "Gall & Inglis (Reckoners) Ltd." But perhaps a more unexpected clue is an even better guide to the probable publishing dates.

The Gall & Inglis main operating base was always Edinburgh but they also had a London office. The role and nature of the London office, apart from possibly acting as a distribution centre, is unknown. However, as the addresses of both locations were usually printed on the flysheet, they provide a handy time-line and range of possible publication years:

- **For Edinburgh**

1857-1878	6 & 8, George Street
1878-1924	20, Bernard Terrace
1924- end	12, Newington Road
- **For London**

1872-1875	30, Paternoster Row, E.C.4
1875-1909	25, Paternoster Square, E.C.4
1909-1930	31, Henrietta Street, W.C.2
1930- end	13, Henrietta Street, W.C.2

In particular, the Edinburgh address of Bernard Terrace and the London addresses in Henrietta Street are good dating guides. For example, any undated Ready Reckoner listing the London address as 13, Henrietta Street must have been published after 1930.

Clearly before metrication and decimalisation the Gall & Inglis Ready Reckoners would have been exported to many of the countries making up the British Empire. There is also some evidence that Gall & Inglis (Reckoners) Ltd., as a trading entity, continued to use established channels to export their titles even after the family business was sold on. For example, Australia went decimal on February 14th 1966. But two years before, in collaboration with Rigby⁶ Limited of Adelaide, R.M.G. Inglis published an "*Australian Dollar Ready Reckoner and Percentage Reckoner*". Gall & Inglis did this despite there being at least one native Australian publisher of Ready Reckoners: Broomhall.

⁶ Founded in the 1950's, Rigby was a major Australian printer/publisher specialising in books for schools.

Fig. 12: (i) Gall & Inglis 1966 Reckoner
(ii) Broomhall's 1914 Reckoner

Response of slide rule manufacturers

By the start of the 20th century the failings of the popular rectilinear slide rule when calculations involved imperial units, fractions or non-decimal units had not gone unnoticed by slide rule manufacturers⁷. This is why many initially glued a variety of paper tables (later sometimes photo-etched into PVC) with conversion factors onto the back of their simplex rules. Having the right conversion factor to hand helped but it still did not simplify the long-winded series of error-prone settings needed, for example, to do longhand calculations with imperial units. Slide rules for calculating with fractions are virtually unknown [13].

Fig. 13: **Home-made 330x47x20mm hexadecimal copper on wood fraction rule [14] – see also "*Best of Both Worlds*"**

Naturally manufacturers based in Britain had an extra "home-grown" incentive to come up with something better than a table of conversion factors. For example, around the 1920's (possibly later), F. Robson & Co.⁸ of Newcastle on Tyne produced a large boxwood slide rule for the steel trade with imperial length (feet and inches) and mass (pounds and hundredweights) based scales.

⁷ Since the 1760's instrument makers did include an imperial foot scale divided into 100 units for calculations involving surface areas and volumes as an edge scale on the majority of Coggeshall rules.

⁸ Little is known about the company or the period in which it made slide rules.

Fig. 14: **F. Robson & Co. 476x42x6mm boxwood rule for the Steel trade**

Much later, probably in the 1950's, Blundell Harling produced a plastograph⁹ steel weight calculator (for Lbs, Qrs, Cwts and Tons¹⁰) for steel stockholders James Austin & Sons Limited of Dewsbury.

Fig. 15: **Blundell Harling 252x42x4mm plastic Steel Weight Calculator**

As decimalisation did not come to the UK (and Republic of Ireland) until February 15th 1971 many manufactures (especially in the UK) carried on designing clever solutions for calculating with the pre-decimal currency. For example, the Unique Monetary rule with the M1/M2/M3 sterling (£ s d¹¹) based scales and the equally innovative¹² M1 to M4 sterling based scales Blundell Harling added to one of their popular Academy range of rules [15].

Fig. 16: **Unique 290 x 36 8mm wood/celluloid Monetary rule [16] and Blundell-Harling 342x49x3.5mm plastic 503D Commerce rule [15]**

⁹ BH name for the engraving, laminating and gluing construction method used for plastic rules – rivets were added as a precaution in case the gluing came unstuck [15].

¹⁰ Abbreviations for imperial units of weight: a pound, a quarter, a hundredweight and a ton.

¹¹ British pre-decimal abbreviations for: pounds (£), shillings (s) and pence (d).

¹² So much so that Blundell Harling applied for a patent (application no. 6225) on it in 1967.

However, apart from rare exceptions like the Keuffel & Escher prototype structural slide rule [17] from the early 1900's, most other leading slide rule manufacturers opted to compete with Ready Reckoners by selectively adding conversion factors as gauge marks [18]. However, it was the German manufacturer, Nestler, who in 1913 introduced the ground-breaking¹³ "System Kaufman" model 40 – the first specialist slide rule designed for merchants [19]. In the same year the American company of Hutton started selling a very similar (possibly made by Nestler) rule [20]. From 1931 Nestler added two extra scales to the early design and over the coming years developed a family of System Kaufmann slide rules. In 1961 it was superseded by the Mercur model 0401.

Fig. 17: **Nestler 275x31.5x9.4mm model 40 (early design) mahogany rule for merchants**¹⁴

In response, other manufacturers started designing new innovative scales. Most of these were incorporated into new rectilinear slide rules in their specialist range. This innovation certainly did not go unnoticed by Nestler's great German rival; Faber-Castell (F-C). In 1923 (revised in 1929) F-C responded with the impressive (size and design) "System Rohrberg" Columbus model 342 [21]. It came with a specially written instruction book. Through the Columbus, Disponent and Bivius series' F-C continued making slide rules for merchants until 1975.

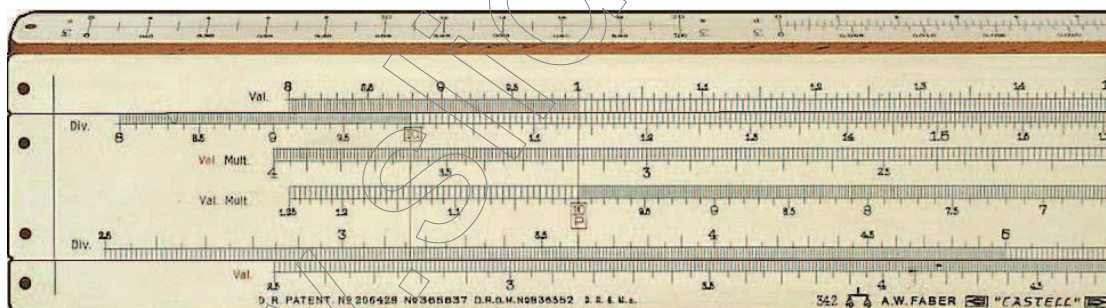

Fig. 18: **Faber-Castell 385x50x12.8mm model 342 pearwood System Rohrberg (1929 design [22]) rule**

Curiously it was Reiss and not the last of the "Big Three" German manufacturers, Dennert & Pape (D&P), which followed the trend set by Nestler and F-C. In 1918 D&P did offer a Valuta C43 model specifically for currency based calculations but it was only two decades later that they, as part of their Aristo Kaufmann (System Dr. Stender) range, really started producing specialist slide rules for merchants. Whereas the Reiss Stellfix K (model 1143) slide rule¹⁵ for merchants, with a frameless "free view" Phoenix cursor, dates from the early 1920's [23].

¹³ Nestler were granted a patent, DRGM 564 729, for it.

¹⁴ In 1922 the Dutch office supplies company, Ahrend, included the Nestler 40 in their assortment of slide rules as the *Ahrend 771*.

¹⁵ Started in 1912, the Stellfix range of mahogany and celluloid rules was renowned for its use of extended root scales and frameless cursors. In the 1920's the Dutch office supplies company, Ahrend, included the Reiss Stellfix K in their assortment of slide rules as the *Ahrend 677*.

It falls outside the scope of this paper but it would be interesting to compare the different innovative design options chosen by the various German manufacturers to increase slide rule sales for trade and commerce.

Best of Both Worlds

However, in true Darwinian fashion the Ready Reckoner was not the “swansong” of the printed calculating aid. Possibly in response to customer requests, some Ready Reckoners evolved into Tabular Calculators and even “hybrid” Calculator Books. The following classification scheme shows how Ready Reckoners and their contemporaries evolved.

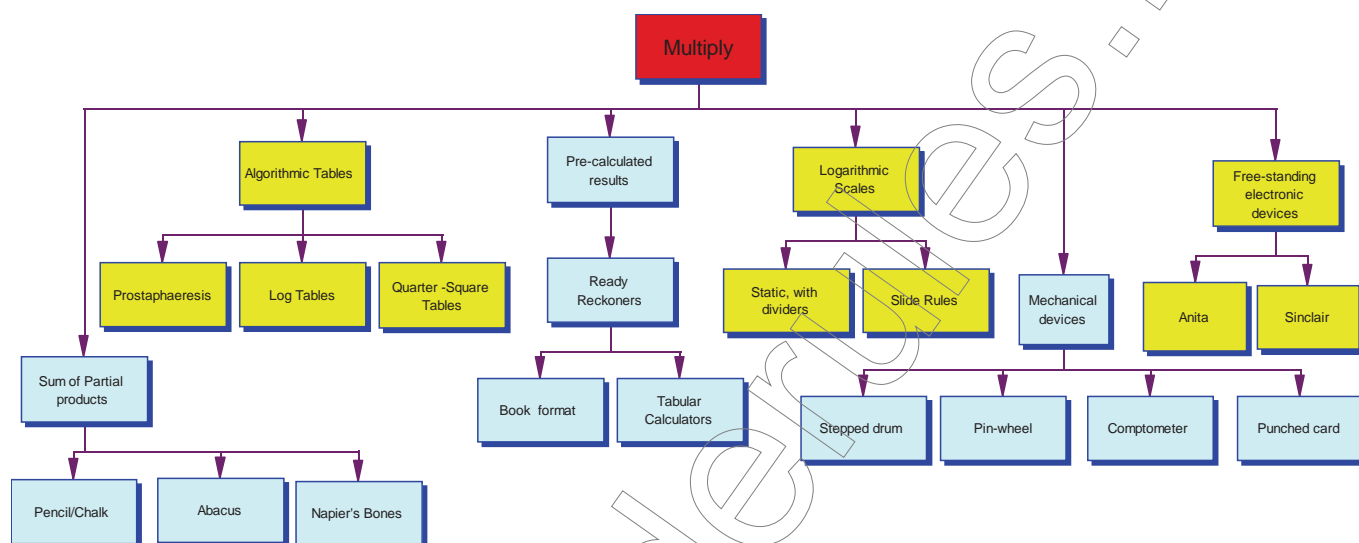

Fig. 19: **Bruce Williams' classification scheme [24]**

Tabular Calculators were an attempt to avoid the sometimes “irritating” page-turning aspect of Ready Reckoners by partially mechanising the process. The page-turning problem was most obvious when, for example, having to work through a series of calculations in mixed units of say pounds, quarters, hundredweights and tons. So pages, or parts of tables, were pasted onto discs, cylinders, drums, etc. Then by “dialling” or some kind of mechanical aid, different parts of the old Ready Reckoner tables automatically lined up to give the result.

Fig. 20: **Simple 220mm paper on wood „HABS” Multiplication Calculator¹⁶**

This simple device has a paper cursor surrounding a finger-thick tube. Juxtaposing any two numbers in red and their product appears in a cursor window. In the example shown, 19×19 (on the right) = 361 (in the left-hand window of the cursor) and 6×9 (on the left) = 54 (in the right-hand window of the cursor). Basically it is a multiplication table for up to 19×20 rolled around a stick. In contrast, the Tariff Calculator provided by Pacific Cable Board, London, SW1 was clearly intended for trade and commerce. It showed the cost of sending a telegram of 1-30 words to various continents and islands around the world.

¹⁶ The instructions are in Dutch but it could be of German origin as the name „HABS” and the D.R.P. suffix (Deutsches Reichspatent) could be derived from the German “*Ich habe es*” or “*I have it*”.

Fig. 21: **Early 1900's Pacific Cable Board 355mm wooden Tariff Calculator for calculating the pre-decimal cost of sending a telegram from the UK**

But with their cross-over hybrid series, combining a Ready Reckoner with a slide rule, Gall & Inglis took this tabulator concept a step further. They were called: **"Inglis' Flash Reckoners"**. Surprisingly the brain behind this innovative hybrid was the apparent "junior partner": H.R.G. Inglis. Apart from being a keen mountaineer (hence the interest in maps and atlases) Harry Inglis appeared uninvolved in the Ready Reckoner side of the business. Indeed when a Ready Reckoner was attributed to a family member, it was to his elder brother, J. Gall Inglis, or later to his nephew: R.M.G. Inglis. None were ever attributed to H.R.G. Inglis. So it is surprising to find his name listed as the inventor on the 1912 patent application. The patent being granted a year and a day later, on 20th January 1913: GB 191201533.

1533. Inglis, H. R. G. Jan. 19.

Slide-rules comprise a base A^2 , two movable slides A , A^1 , and an indicator C attached to one slide and extending transversely so as to co-operate with the graduations on the other slide. The usual graduations are in some cases replaced by special marks or signs; these are shown in Fig. 3.

(For Figures see next column.)

Fig. 22: **Original January 19th 1912 patent application for a multi slide rule [25]**

But despite being credited as the publishers on all *Flash Reckoners*, intriguingly the Gall & Inglis company name is not mentioned anywhere in the patent application. However, the Edinburgh address always listed for the *Flash Reckoners* is 20, Bernard Terrace. But as Gall & Inglis were only based at this address from 1878-1924 and the original patent dates from 1912, suggests the Inglis' *Flash Reckoner* only had a brief 1912-1924 or 12-year publication life span. Nevertheless Gall & Inglis published a whole series (see the *Appendix*). One of the earliest, for engineers, innovatively even had scales for fractions as well as decimals.

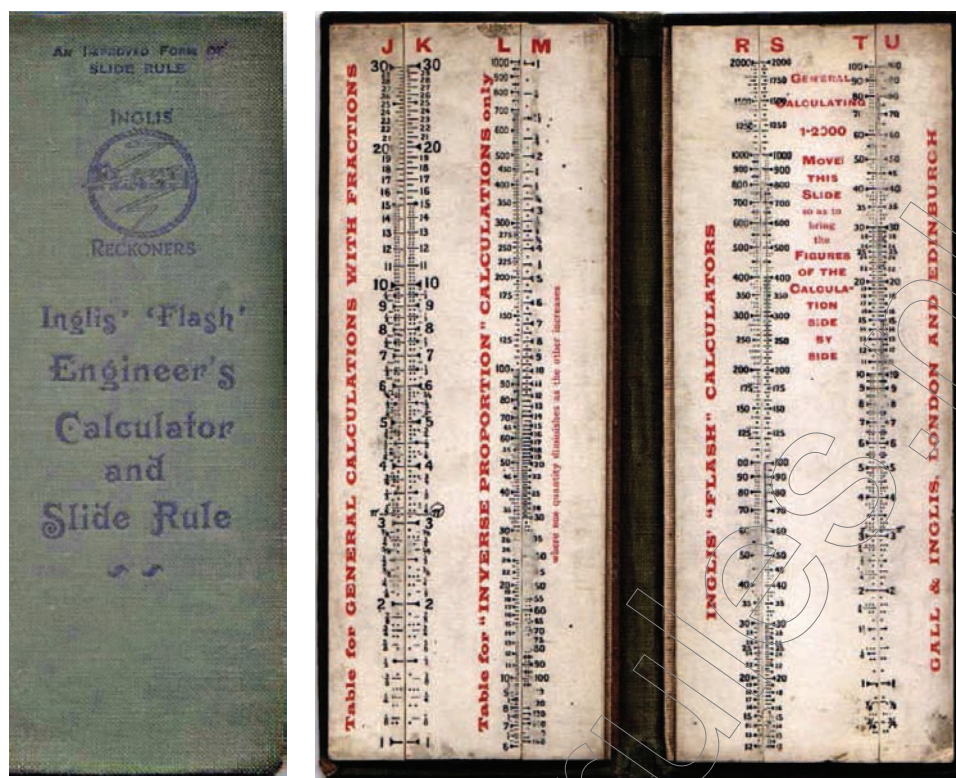

Fig. 23 **Inglis' Flash Reckoner - Engineers' Calculator and Slide Rule** [26]

To increase legibility sometimes Gall & Inglis replaced linear scale divisions with symbols or gauge marks and added a fixed pointer that acted as a crude cursor.

Fig. 24: **Inglis' 243x80x6mm Flash Reckoner - Bank Interest Calculator**

Clearly these hybrids would have been much trickier and more complicated to print and bind than other Gall & Inglis publications. They would also have been more complicated to use than a conventional printed Ready Reckoner. Moreover, by their nature, the scale ranges had to be compacted and this meant their overall accuracy was far inferior to a normal Ready Reckoner. Indeed on the inside cover "Introduction" speed rather than accuracy was always stressed.

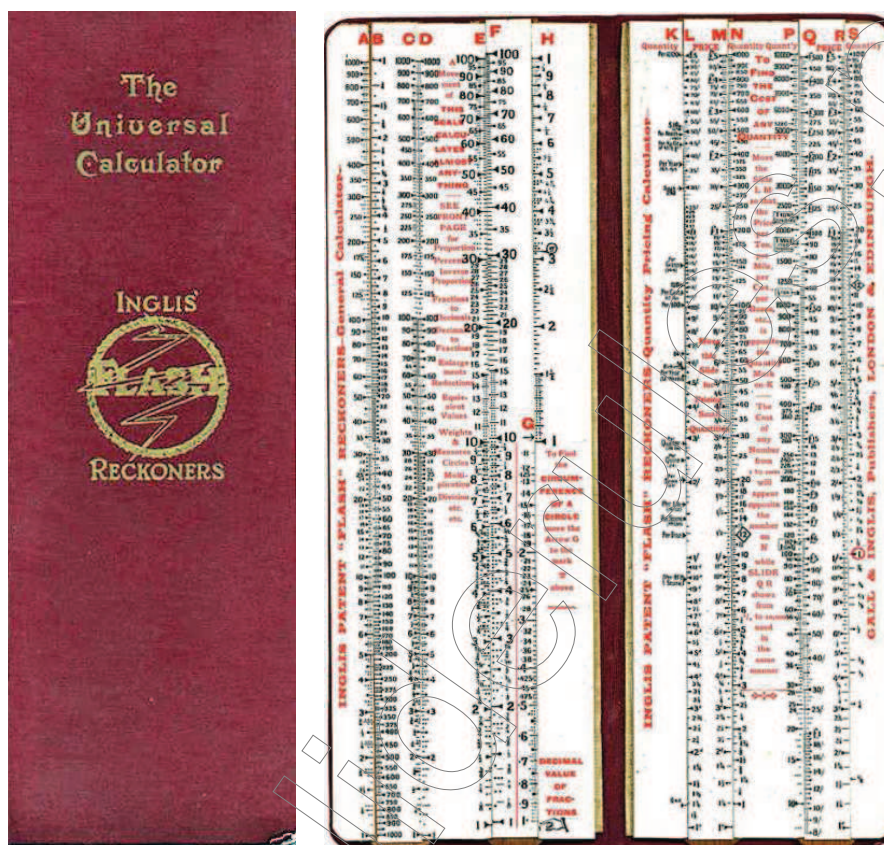

Fig. 25: Inglis' 243x80x6mm *Flash Reckoner* - Universal Calculator

So maybe when Gall & Inglis moved their main Edinburgh premises to 12, Newington Road in 1924, the company decided to rationalise their portfolio of titles or their printing and binding equipment? It certainly remains a mystery why such an innovative and patented idea was dropped by Gall & Inglis and no new editions were published after 1924. Perhaps the limited accuracy of the Inglis' *Flash Reckoners* was the ultimate reason for their short run?

So you can Reckon on it!

Although some were still being made right up to the the 1970's, the sales volume of specialist slide rules for merchants never made much impression on the millions of Ready Reckoners bought for trade and commerce. To compensate most slide rule manufacturers had, over time, at least added conversion tables and suitable gauge marks to their rules. Consequently slide rule collectors should not, for example, dismiss lightly the significance of a humble paper conversion chart stuck on the back of any slide rule.

For the 19th and most of the 20th century, all over the world, shop assistants, wage clerks, etc relied on their Ready Reckoners. The Scottish publishing dynasty of Gall & Inglis was instrumental in providing millions of the inexpensive pocket-sized printed aids needed for them to perform so many error-free calculations daily. Most modern-day owners of Personal Digital Assistants (PDA's) have probably never heard of a Ready Reckoner. Ironically the reason PDA's are so popular is similar to the reason Ready Reckoners became so popular in their day!

So despite being largely a British trait, the humble but immensely popular Ready Reckoner rightly deserves a place in the "hall of fame" of calculating aids alongside the slide rule. Collectors should look out for the rare hybrids from the Gall & Inglis *Flash Reckoner* series as they would certainly grace any slide rule collection.

Dedication and Acknowledgements

I dedicate this paper to UKSRC member Bruce Williams. It was Bruce's presentation at the IM2003 [24] that seeded my interest in Ready Reckoners and provided the inspiration to write this paper. Regrettably, following a serious illness, Bruce's previous prodigious output is now somewhat curtailed and he can no longer pursue his many avenues of slide rule related research. I just hope this paper, in some small way, is a fitting tribute to the keen mind of a great collector and researcher.

Naturally many people helped me with my research along the way. Most of you know who you are, but I would particularly like to thank (in alphabetical order):

- **Dr David Gavine** for invaluable work in tracking down the Gall-Inglis family details from Register House, Edinburgh – without this help it would have been impossible to trace and build the "Gall & Inglis family tree",
- **Leo de Haan** for permission to use information and reproduce tables from his article (in Dutch) on English units of measurement – this saved me many, many hours of work,
- **Ray Hems** for information and images,
- **Peter Hopp** for many helpful suggestions and acting as an intermediary to Bruce Williams and his past research,
- **John Hunt Snr** for information and images,
- **Werner Rudowski** for information and images.

Answers to calculations involving imperial units:

- From the Haberdasher: **9s 4¾p**
- From the Ironmonger: **2s 6p or half-a-crown**
- From the Chancery: **£75 0s 0p or 75 quid**

Appendix – The Ready Reckoners of Gall & Inglis

Apart from a single copy from 1958 held by the National Library of Scotland, no other Gall & Inglis catalogues are known to exist. So this Appendix (listed chronologically by approximate date) has been compiled by collating the few snippets of information that were available, entries in the 1958 catalogue and from the author's modest collection of Ready Reckoners.

Consequently it is almost certainly incomplete and is, at best, just work-in-progress!
